Let x_n be a sequence of positive real numbers such that $\lim_n x_n = x > 0$. Prove that

- $\bullet \lim_n x_n^2 = x^2.$
- $\lim_n \sqrt{x_n} = \sqrt{x}$.

Part 1: Using the identity

$$x_n^2 - x^2 = (x_n - x)^2 + 2x(x_n - x)$$

Where for any given $\varepsilon > 0$ there exists an integer N such that for any $m \geq N$, $|x_m - x| < \sqrt{\varepsilon}$. This implies that $|(x_n - x)^2| < \varepsilon$ and therefore $\lim_{n \to \infty} (x_n - x)^2 = 0$. And clearly

$$\lim_{n \to \infty} 2x(x_n - x) = 2x \cdot 0 = 0$$

Thus $\lim_n x_n^2 - x^2 = \lim_n (x_n - x)^2 + 2x(x_n - x) = 0$ and therefore

$$\lim_{n} x_n^2 = x^2$$

Part 2:

By what was given, one need not consider the cases where $x \leq 0$. If x > 0 then there exists an N such that if $m \geq N$, $|x_m - x| < \varepsilon \sqrt{x}$. Then, because this is over positive real numbers,

$$|\sqrt{x_m} - \sqrt{x}| = \frac{|x_m - x|}{|\sqrt{x_m} + \sqrt{x}|} < \frac{|x_m - x|}{\sqrt{x}} < \frac{\varepsilon\sqrt{x}}{\sqrt{x}} = \varepsilon$$

Thus $\lim_{n} \sqrt{x_n} = \sqrt{x}$.

Define a sequence by $s_1 = 1$ and $s_{n+1} = \sqrt{2 + \sqrt{s_n}}$. Prove that $s_n < 2$ for all n, and that s_n is an increasing sequence. Find the limit.

To begin, one sees immediately that s_n increases between $s_1 = 1$ and $s_2 = \sqrt{3}$. Suppose that s_n is increasing from n = 1, ..., m. Then,

$$s_{m} = \sqrt{2 + \sqrt{s_{m-1}}} > s_{m-1}$$

$$\sqrt[4]{2 + \sqrt{s_{m-1}}} > \sqrt{s_{m-1}}$$

$$2 + \sqrt[4]{2 + \sqrt{s_{m-1}}} > 2 + \sqrt{s_{m-1}}$$

$$\sqrt{2 + \sqrt[4]{2 + \sqrt{s_{m-1}}}} = s_{m+1} > \sqrt{2 + \sqrt{s_{m-1}}} = s_{m}$$

Hence $s_{m+1} > s_m$. Thus the sequence is increasing for all $n \ge 1$. Next, suppose that some $s_m \ge 2$. Then,

$$2 \le \sqrt{2 + \sqrt{s_{m-1}}}$$

$$4 \le 2 + \sqrt{s_{m-1}}$$

$$2 \le \sqrt{s_{m-1}}$$

$$4 < s_{m-1}$$

Thus, if $s_m \geq 2$ then $s_{m-1} \geq 4$. But this contradicts the fact that the sequence is strictly increasing. Thus $s_n < 2$ for all $n \geq 1$. To find the limit of the sequence, let $\lim_n \sqrt{2 + \sqrt{s_n}} = L$. Then

$$L = \sqrt{\lim_{n} (2 + \sqrt{s_n})} = \sqrt{2 + \lim_{n} \sqrt{s_n}} = \sqrt{2 + \sqrt{\lim_{n} s_n}} = \sqrt{2 + \sqrt{L}}$$

Thus the limit will be a solution to the expression above, or when rearranged:

$$L^4 - 4L^2 - L + 4 = 0$$

Which is approximately 1.83118, or in exact form:

$$\frac{1}{3}\left(-1+\sqrt[3]{\frac{1}{2}(79-3\sqrt{249})}+\sqrt[3]{\frac{1}{2}(79+3\sqrt{249})}\right)$$

Let $X = \mathbb{Z}$ and d(x, x) = 0 or $d(x, y) = \frac{1}{2^n}$, if $x \neq y$, where 2^n is the largest power of 2 dividing x - y. Prove that the following two series are Cauchy. One of them is convergent (find its sum) while the other not (explain).

- $\bullet \ \sum_{n=0}^{\infty} 2^n$
- $\bullet \ \sum_{n=0}^{\infty} (-2)^n$

To begin, let s denote the first series, and let r denote the second. Consider two nonequal partial sums s_n , and s_m . Then,

$$s_n = 2^0 + 2^1 + \dots + 2^n$$

 $s_m = 2^0 + 2^1 + \dots + 2^m$

Without loss of generality, assume m > n. Then,

$$s_m - s_n = 2^{n+1} + \dots + 2^m$$

= $2^{n+1} (1 + 2^1 + \dots + 2^{m-n-1})$

Thus the differences between any two nonequal partial sums of degrees m and n with m > n is $\frac{1}{2^{n+1}}$. If n = m then the distance is zero, by definition. One can easily see that the same is true for r by simply replacing any 2 in the steps above with (-2) and then factoring out 2^{n+1} at the very end.

With this is it very straightforward to show that both series are Cauchy. Given any $\varepsilon > 0$ one can find a j such that $0 < \frac{1}{2^j} < \varepsilon$ and $\varepsilon \le \frac{1}{2^{j+1}}$. Without loss of generality, take any partial sum of degree k > j of s, then

$$d(s_k, s_j) = \frac{1}{2^{j+1}} < \varepsilon$$

It is very easy to see that the statement above is equally true for r. Hence, both series are Cauchy.

Although both are Cauchy, only s is convergent, and it converges to -1. The reason is through considerations of the limit of the similar sequence $\lim_{n\to\infty} 2^n$. One sees that the distance between 0 and any 2^n is $\frac{1}{2^n}$ since 0 is divisible by any integer. Hence,

$$\lim_{n \to \infty} d(0, 2^n) = \lim_{n \to \infty} \frac{1}{2^n} = 0$$

Thus $\lim_{n\to\infty} 2^n = 0$ and since any partial sum of $s, s_n = 2^{n+1} - 1$,

$$\lim_{n \to \infty} s_n = \lim_{n \to \infty} 2^{n+1} - 1 = 0 - 1 = -1$$

The other series r does not converge because the valuations of its partial sums do not tend to $+\infty$ or eventually stabilize to some constant sequence.

Question 4

Let c_n be a sequence of positive numbers. Prove that

$$\liminf_{n} \frac{c_{n+1}}{c_n} \le \liminf_{n} \sqrt[n]{c_n}.$$

Proof. Let $\alpha' = \liminf_n \sqrt[n]{c_n}$ and $\alpha = \liminf_n \frac{c_{n+1}}{c_n}$. Also let B be an arbitrary positive number such that $B < \alpha$ and let $z_m = \liminf_{m \ge n} \frac{c_{m+1}}{c_m}$. Then $\exists N$ such that $z_N \ge B$ for all $m \ge N$. In other words we have,

$$B \le \frac{c_{N+1}}{c_N}, B \le \frac{c_{N+2}}{c_{N+1}}, \cdots, B \le \frac{c_{m+1}}{c_m}$$

Or,

$$c_{N+1} \ge Bc_N, c_{N+2} \ge B^2 c_N, \cdots, c_m \ge B^{m-N} c_N$$

So then in another form, $c_m \geq \frac{c_N}{B^N} B^m$. Then we also have that

$$\sqrt[m]{c_m} \ge \sqrt[m]{\frac{c_N}{B^N}B^m}$$

However note that $\frac{c_N}{B^N}$ is constant, so as m increases, the value of the m-th root of the quotient approaches 1, so we then have

$$\sqrt[m]{c_m} \ge \sqrt[m]{\frac{c_N}{B^N}B^m} \to \sqrt[m]{B^m} = B$$

Thus for all $B < \alpha, \alpha' \ge B$. This implies that $\alpha' \ge \alpha$. In other words,

$$\liminf_{n} \sqrt[n]{c_n} \ge \lim\inf_{n} \frac{c_{n+1}}{c_n}.$$

Let (X, d) be a metric space. Let $x = \{x_n\}$ and $y = \{y_n\}$ be two Cauchy sequences. Prove that the sequence of distances $d(x_n, y_n)$ is a Cauchy sequence of real numbers.

Proof. Since $\{x_n\}$ and $\{y_n\}$ are both Cauchy, it is true that for any $\varepsilon > 0$, $\exists N$ such that $d(x_n, x_m) < \frac{\varepsilon}{2}$ for all $m \geq N$ (and likewise for $\{y_n\}$). Then because X is a metric space,

$$d(x_n, y_n) \le d(x_n, x_m) + d(x_m, y_m) + d(y_m, y_n) \tag{1}$$

$$d(x_n, y_n) < \frac{\varepsilon}{2} + d(x_m, y_m) + \frac{\varepsilon}{2}$$
(2)

By rearranging (2) we get

$$d(x_n, y_n) - d(x_m, y_m) < \varepsilon$$

And by multiplying (1) by -1 and rearranging, we find that

$$d(x_m, y_m) - d(x_n, y_n) > -\varepsilon$$

Which implies that

$$|d(x_n, y_n) - d(x_m, y_m)| < \varepsilon$$

And since this is the standard distance formula for the real numbers, this shows that the sequence of distances $d(x_n, y_n)$ is a Cauchy sequence in \mathbb{R} . \square

Let (X, d) be a metric space. Two Cauchy sequences $x = \{x_n\}$ and $y = \{y_n\}$ are equivalent if for every $\epsilon > 0$, there exists n such that $d(x_m, y_m) < \epsilon$ for all $m \ge n$. Prove that this is an equivalence relation.

Proof. Since X is a metric space, d(x, x) = 0 with any $x \in X$. Hence for any sequence $\{x_n\}$

$$d(x_m, x_m) = 0 < \varepsilon$$

Thus $\{x_n\}$ is equivalent to itself, and thus the relation is reflexive. Next, suppose a sequence $x = \{x_n\}$ was equivalent to another sequence $y = \{y_n\}$. Then since X is a metric space,

$$d(y_m, x_m) = d(x_m, y_m) < \epsilon$$

Hence y is equivalent to x and is therefore a symmetric relation. Now suppose a sequence $x=\{x_n\}$ was equivalent to another sequence $y=\{y_n\}$ and suppose that y was equivalent to another sequence $z=\{z_n\}$. Then there exists an N_1, N_2 such that $d(x_m, y_m) < \frac{\varepsilon}{2}$ and $d(y_m, z_m) < \frac{\varepsilon}{2}$ for $m \ge max(N_1, N_2)$. Then since X is a metric space,

$$d(x_m, z_m) \le d(x_m, y_m) + d(y_m, z_m)$$

$$d(x_m, z_m) < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon$$

therefore x and z are also equivalent and the relation is transitive. Since the relation is reflexive, symmetric, and transitive, the relation defines an equivalence relation.

Let Y be a non-empty set and $d: Y \times Y \to [0, \infty)$ a "distance" function such that

- d(x,x) = 0 for all $x \in Y$.
- d(x,y) = d(y,x) for all $x, y \in Y$.
- $d(x,z) \le d(x,y) + d(y,z)$ for all $x, y, z \in Y$.

In words, d is almost a distance function, however, d(x,y) = 0 is allowed for different x and y. We say that x and y are equivalent if d(x,y) = 0. (1) Prove that this is an equivalence relation. (2) Prove that, if x is equivalent to y then d(x,z) = d(y,z) for all $z \in Y$.

Proof. Reflexivity and symmetry are given. All that is left to show is transitivity. Let x be equivalent to y and y be equivalent to z. Then,

$$d(x,z) \le d(x,y) + d(y,z)$$

And since x and y are equivalent,

$$d(x,z) \le 0 + d(y,z) = d(y,z)$$

So $d(x, z) \leq d(y, z)$. Now instead consider d(y, z)

$$d(y,z) \le d(y,x) + d(x,z)$$

$$\le d(x,y) + d(x,z)$$

$$< 0 + d(x,z)$$

So we have $d(x, z) \leq d(y, z)$ and $d(y, z) \leq d(x, z)$. Thus d(x, z) = d(y, z), immediately proving (2). However if y and z are equivalent, then d(y, z) = 0. So then in the case above, d(x, z) = d(y, z) = 0, meaning that x must be equivalent to z, proving transitivity, and therefore that the relation is an equivalence relation.
